Modern illness or a thing of the past?
Surveillance study of childhood/adolescent Sydenham’s chorea

WHAT IS SYDENHAM’S CHOREA?
Chorea is the term for abnormal movements described as rapid, irregular, aimless and involuntary. The most common cause of childhood chorea is Sydenham’s chorea (SC), which is often accompanied by psychiatric symptoms such as obsessions and compulsions.

The condition is associated with prior infection with the bacteria streptococcus. Symptoms can range from mild to severe, and may impact on the child’s ability to carry out activities of daily living. Psychiatric disorders triggered by SC may be long-lasting and disabling. Whilst SC may resolve within six months, it can follow a relapsing course for up to two years or longer.

THE SYDENHAM’S CHOREA SURVEILLANCE STUDY
Little is known about how frequently SC now occurs in the UK and the Republic of Ireland (ROI) or how often it may relapse. Given the impact on the lives of patients and families, there is a clear need for a prospective study of new cases. We have been working with the family charity the Sydenham’s Chorea Association to develop this research.

The aim of this study is to examine the current pattern and presentation of the disorder, raise awareness and inform the planning of services.

We are carrying out this study in parallel with surveillance through the British Paediatric Surveillance Unit (BPSU), as children may present to paediatricians and/or psychiatrists. Together, our findings will fill the gap in scientific knowledge about the current pattern of SC in the UK and Ireland. This will support service development and planning, contribute to improving recognition of the disorder and facilitate pathways to appropriate investigation and treatment.

HOW LONG WILL IT GO ON FOR?
The study will collect information on cases of SC for 13 months with some information requested at one and two-year follow-up. Thus, the study will last 37 months in total.

WHO SHOULD BE CONTACTED IF I HAVE ANY QUESTIONS ABOUT THIS STUDY?
Please contact CAPSS:

CASE DEFINITION

Please report children and young people aged 0-16 years who have or have had a suspected or confirmed diagnosis of Sydenham’s chorea (e.g. by a paediatrician) and present to you for the first time within the current episode of care (regardless of whether this is their first contact with CAMHS or not) with one or more psychiatric symptoms.

Please report any case even if you believe the case may have been reported from elsewhere.

SC is a post-streptococcal autoimmune movement disorder defined as purposeless, involuntary, non-stereotypical movements of the trunk or extremities, often associated with muscle weakness and emotional lability. It is frequently a clinical diagnosis (absence of laboratory confirmation of streptococcal infection does not preclude clinical confirmation).

Cases may be either:

**Suspected:** cases presenting with chorea but no diagnosis of SC has yet been made.

**Confirmed:** cases where a diagnosis of SC has been made and alternative causes have been excluded.

**Duration**

May 2019 to May 2022

**Lead investigators:** Dr Oana Mitrofan, Consultant in Child and Adolescent Psychiatry and University of Exeter Associate, and Dr Tamsin Newlove-Delgado, Academic Clinical Lecturer and Honorary Consultant in Public Health

University of Exeter Medical School, Room 2.06, College House, St Luke’s Campus, Exeter EX1 2LU

Email: t.newlove-delgado@exeter.ac.uk or o.mitrofan@nhs.net

**Co-investigators** Dr Michael Morton, Dr Ming Lim, Professor Tamsin Ford, Professor Mary King, Dr Brodie Knight, Mr Andrew Samuel, Professor Sameer Zuberi, Ms Catriona Clark

**Research practitioners at Devon Partnership NHS Trust:** Stacey Horne and Tanja Christensen
